

Drug-Induced Liver Injury (DILI) with Severe Transaminase Elevation Associated with High-Dose SynthoStatin

Marcus Richardson, MD; Patricia Kelly, MD; Liver Center, United States

ABSTRACT

Drug-induced liver injury is a critical adverse event in pharmacovigilance. We present a 64-year-old female who developed acute hepatotoxicity with marked ALT/AST elevation following SynthoStatin 40mg daily.

CASE PRESENTATION

A 64-year-old female patient (Weight: 70 kg, Height: 165 cm) presented with jaundice, dark urine, and fatigue. She had been prescribed oral SynthoStatin 40mg daily starting on 01 Aug 2026. On 20 Aug 2026, routine blood tests demonstrated ALT 420 U/L and AST 360 U/L (elevated transaminases). SynthoStatin was discontinued immediately (Outcome: Recovering). Seriousness was graded as Serious due to hospitalization. Documented by Dr. Richardson, Hepatologist.

DISCUSSION

Idiosyncratic hepatotoxicity remains a key safety signal. Early biomarker monitoring is essential for patient protection.
